User Story : Pharmacy Management

As a pharmacist, I want to automatically update medication inventory when dispensing prescriptions so that our stock levels remain accurate and we can proactively manage reordering to prevent stockouts .

Acceptance Criteria

Acceptance Criterion 1: Automatic Inventory Deduction

- Given the current inventory of "Amoxicillin 500mg" is 100 units in the system
- When I process a prescription and dispense 30 units of "Amoxicillin 500mg" to a patient
- Then the system automatically updates the inventory level to 70 units and logs the transaction with timestamp, patient ID, and pharmacist ID

Acceptance Criterion 2: Low Stock Alert Generation

- Given a medication's inventory level falls below the predefined minimum threshold (e.g., 20 units)
- When the system updates inventory after dispensing
- Then the system generates an automatic low stock alert and adds the medication to the reorder list with suggested quantity

Acceptance Criterion 3: Prescription Validation Before Dispensing

- Given I am processing a prescription for a specific medication and quantity
- When I attempt to dispense more units than currently available in inventory
- Then the system prevents the transaction and displays an "Insufficient Stock" warning with current available quantity

Acceptance Criterion 4: Batch and Expiry Date Tracking

- Given medications are stored with batch numbers and expiry dates
- When I dispense medication from inventory
- Then the system automatically selects items using FIFO (First In, First Out) method and updates batch-specific inventory levels
